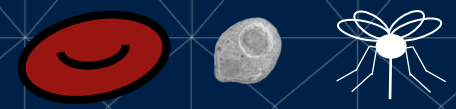
The genetics of susceptibility to malaria

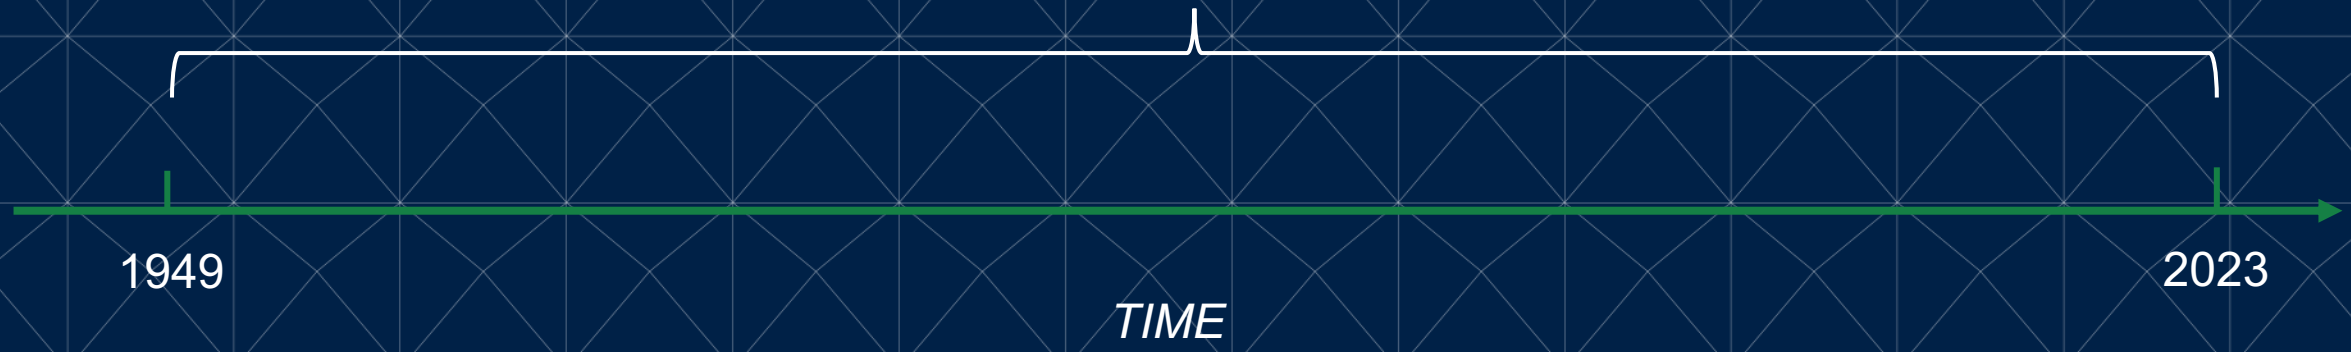
Gavin Band

Adelphi Genetics Forum

Wednesday 18th October 2023

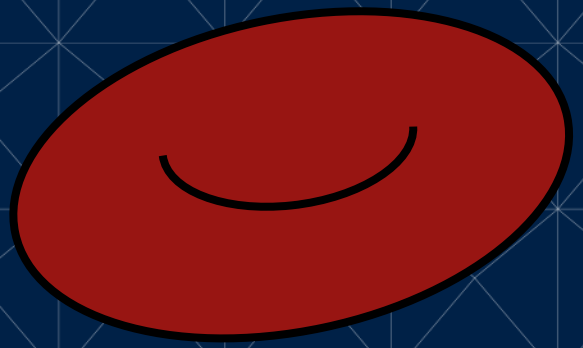


75 years
in
30 minutes

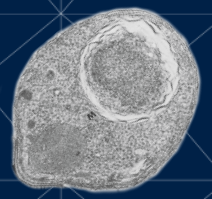


A tale of three genomes

Anopheles mosquitos



Human host



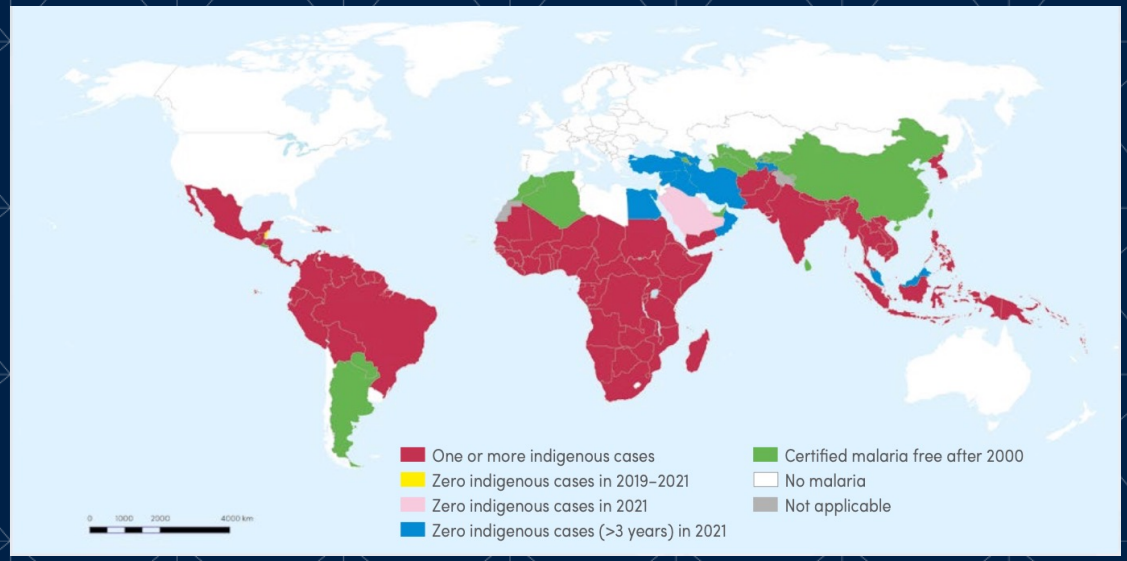
Plasmodium falciparum
(malaria parasite)

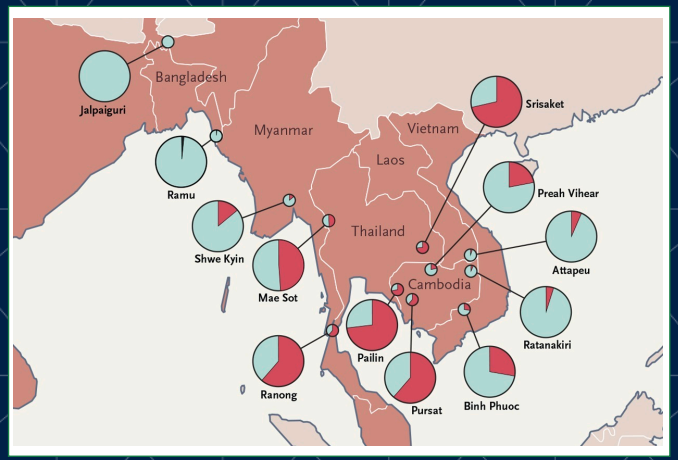
also *P.vivax*, *P. malariae*, *P.ovale*

Reasons to be optimistic

Several countries have eliminated malaria, several more on course to do so by 2025

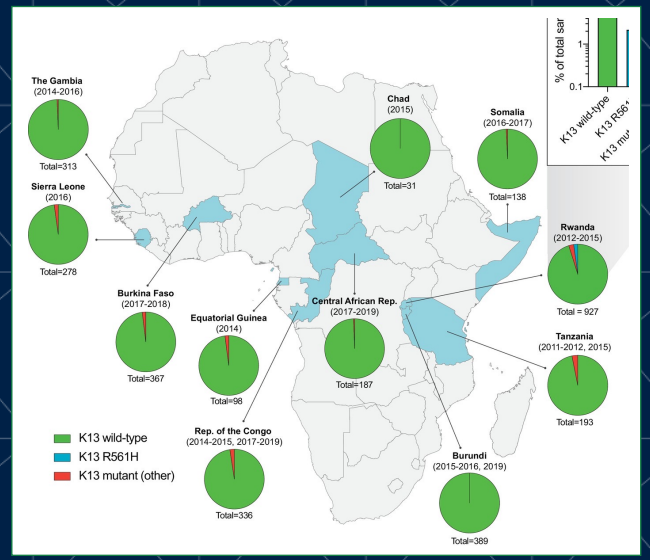
WHO World Malaria Report 2022





Reasons to be concerned

Rising antimalarial and insecticide resistance, including in Africa

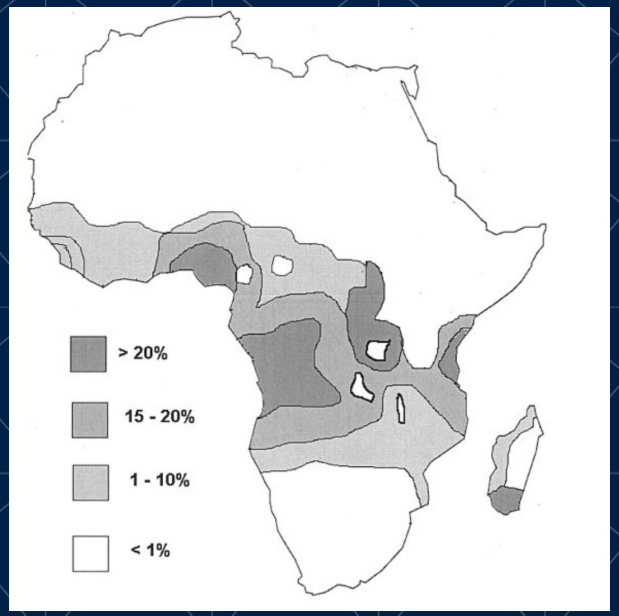


Ashley et al, N. Engl. J. Med. 2014, Stokes et al, eLife 2021

Talk outline

The malaria hypothesis

Distribution of *P.falciparum* malaria in Africa



Distribution of sickle heterozygotes in Africa

"Montalenti [recalled] a gene, lethal in the homozygous state, which occurs in the heterozygous state with such frequency in some populations (more than 10%) that one must admit that it represents [..] an advantage for individuals that carry it"

- transcript of 1949 meeting between J.B.S Haldane and G. Montalenti

"1949 was an annus mirabilis when the modern phase of research on haemoglobinopathies was initiated. […] Montalenti observed high frequencies of thalassemia heterozygotes in formerly malarious parts of Italy, and I observed high frequencies of sickle-cell heterozygotes in formerly malarious parts of Kenya.

- A.C.Allison

P.W. Hedrick, Heredity (2011)
A. C. Allison - Biochem molecular biology education (2006)

TABLE I

	With Parasitaemia	Without Parasitaemia	Total
Sicklers	12 (27·9%)	31 (72·1%)	43
Non-sicklers ..	113 (45·7%)	134 (53·3%)	247

Allison A. C. BMJ (1954)

The discovery of the protective effect of sickle haemoglobin.

Infection observed at ~2-fold lower rates in A/S individuals in this sample of children from Uganda (N = 290)

TABLE I

	With Parasitaemia	Without Parasitaemia	Total
Sicklers	12 (27·9%)	31 (72·1%)	43
Non-sicklers ..	113 (45·7%)	134 (53·3%)	247

Allison A. C. BMJ (1954)

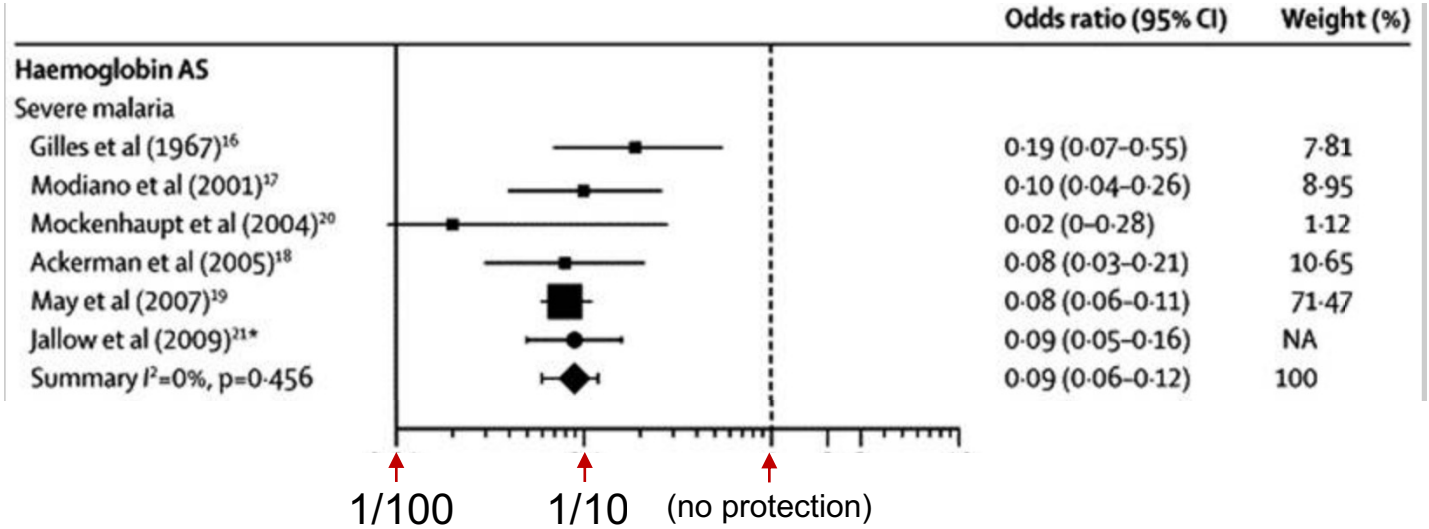
The discovery of the protective effect of sickle haemoglobin.

Infection observed at ~2-fold lower rates in this sample of children from Uganda (N = 290)

Effect size against *severe malaria* is stronger – a 10-fold protective effect .

Now replicated across many populations and studies.

In severe malaria cases:



Taylor et al Lancet Infect. Dis 2013

The malaria hypothesis

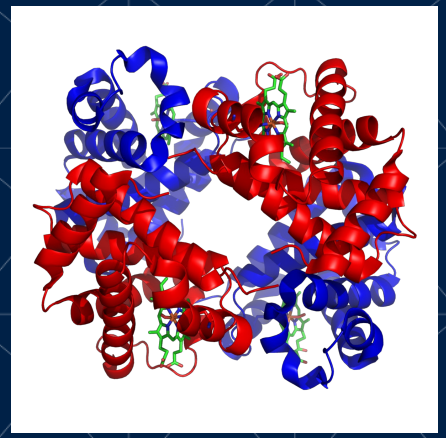
"In the less malarious parts of Accra about 5% of children died from malaria before they were 5 years old [..] fairly evenly spread over the first five years of life. In the more malarious suburban areas, there were many more deaths from malaria in the first two years of life"

- Colbourne M.J. and Edington G.M., BMJ 1956

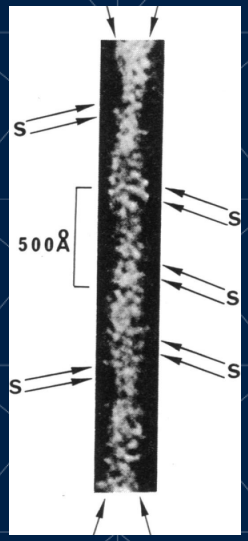
Malaria provides a *positive selective force* on these human genetic alleles – pushing them to higher frequency.

Sickle homozygotes and heterozygots

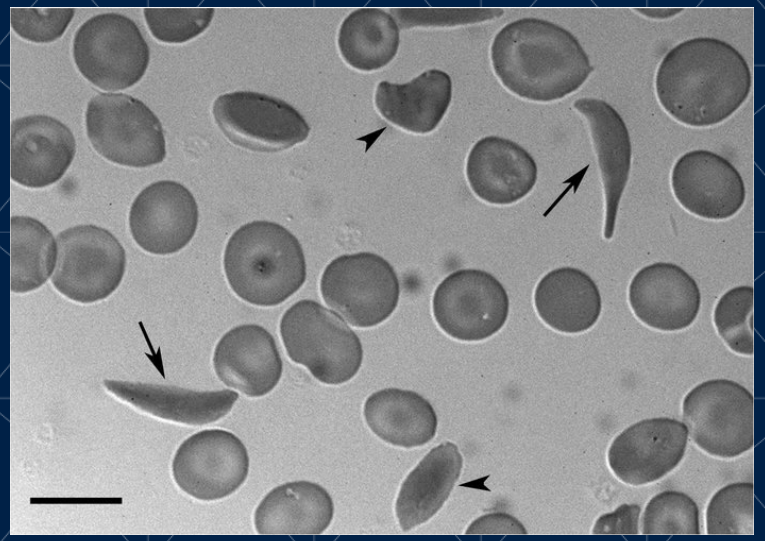
Sickle cell anaemia aetiology is well understood…



Haemoglobin



Edelstein 1973



P.S. Frenette and G.F. Atweh, JCI (2007)

…but it's still not really understood how sickle heterozygotes are protected
although many mechanisms have been proposed

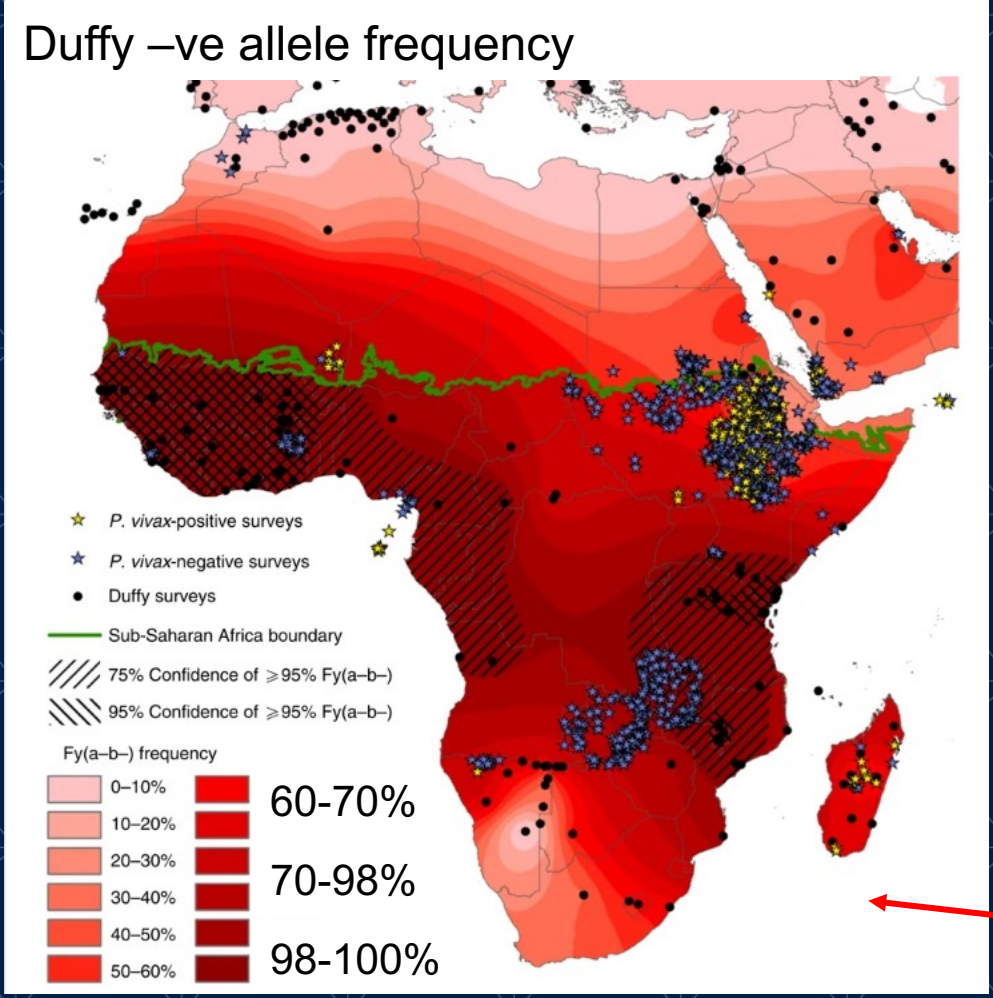
The malaria hypothesis

Malaria provides a *positive selective force* on these human genetic alleles – pushing them to higher frequency.

Anaemia causes a *negative* selective force.

What would happen if this balancing force wasn't there?

The sweep of protection against *P.vivax*



…CCAA**GATA**AGAGC…

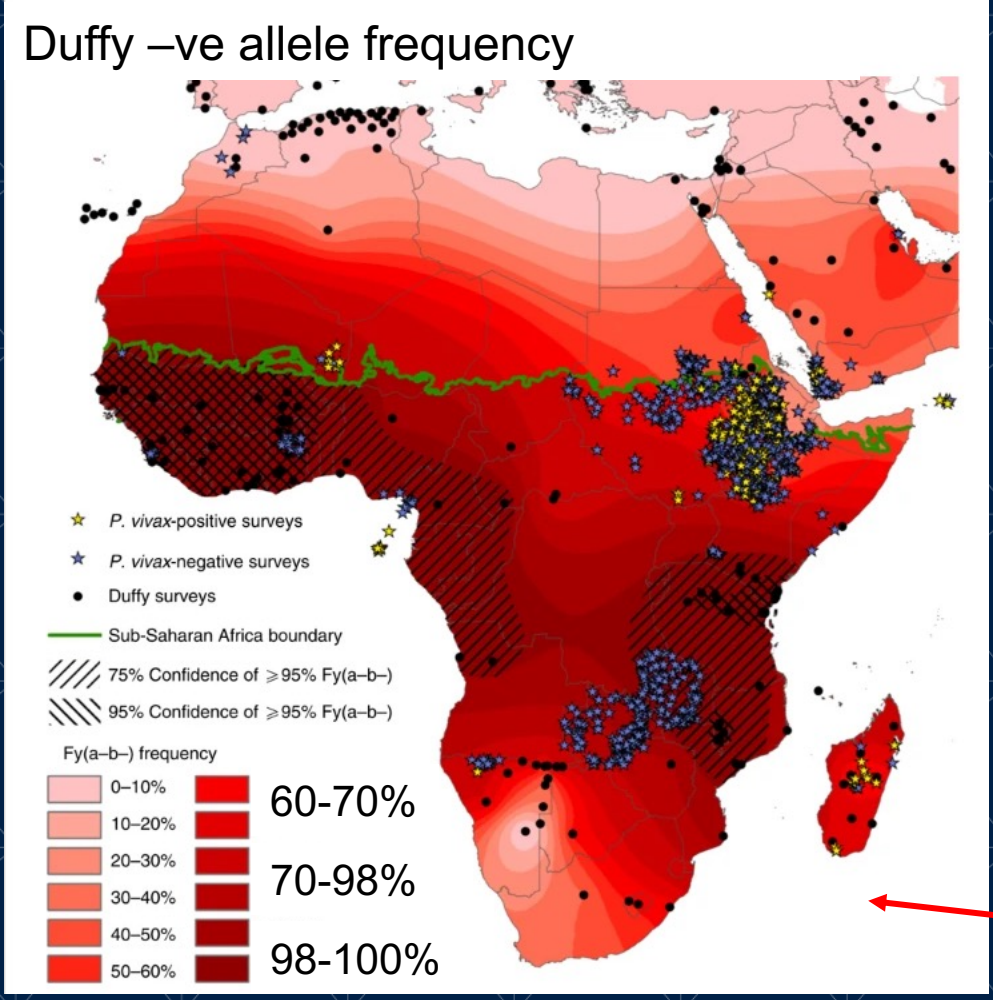
Gene expressed

The GATA transcription factor binds to a DNA motif upstream of the *DARC* gene, causing gene expression

One of the few examples of a selective sweep in the human genome

Rosalind R. Howes et al, Nat. Comm. 2011

The sweep of protection against *P.vivax*



…CCAA**GATA**AGAGC…

DARC

Gene expressed

…CCAAGGTAAGAGC…

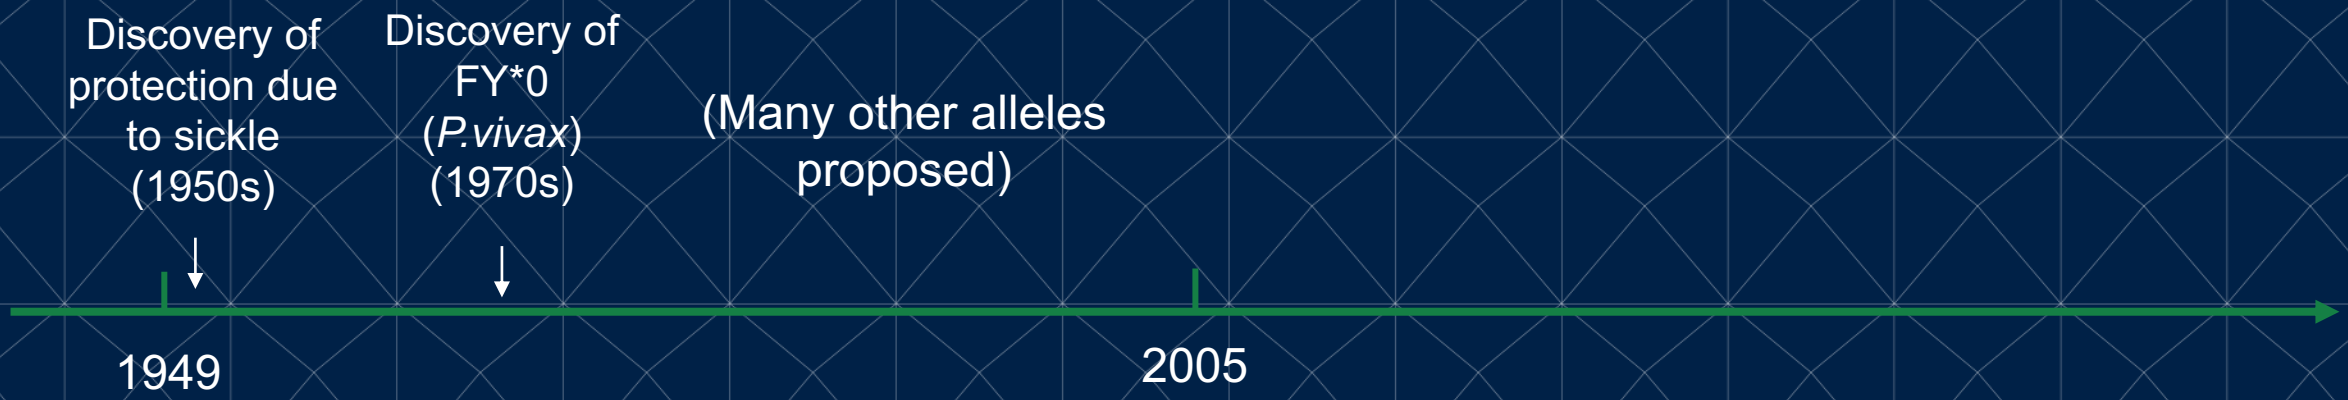
DARC

Gene not expressed

The ‘FY*0’ mutation ‘turns off’ expression by disrupting the GATA site.

One of the few examples of a selective sweep in the human genome

Rosalind R. Howes et al, Nat. Comm. 2011



"How Malaria Has Affected the Human Genome and What Human Genetics Can Teach Us about Malaria"
– Dominic Kwiatkowski Am J Hum Genet 2005

Genetic variants proposed to provide protection circa 2005

: *Beta-globin* HbS, HbC, HbE β - thalassaemia; *Alpha-globin* α - thalassaemia; Glycophorin A and B deletions; *G6PD* deficiency; "Band 3" ovalocytosis; *(DARC For P.vivax)*

Haptoglobin; O blood group; *PIEZO1*

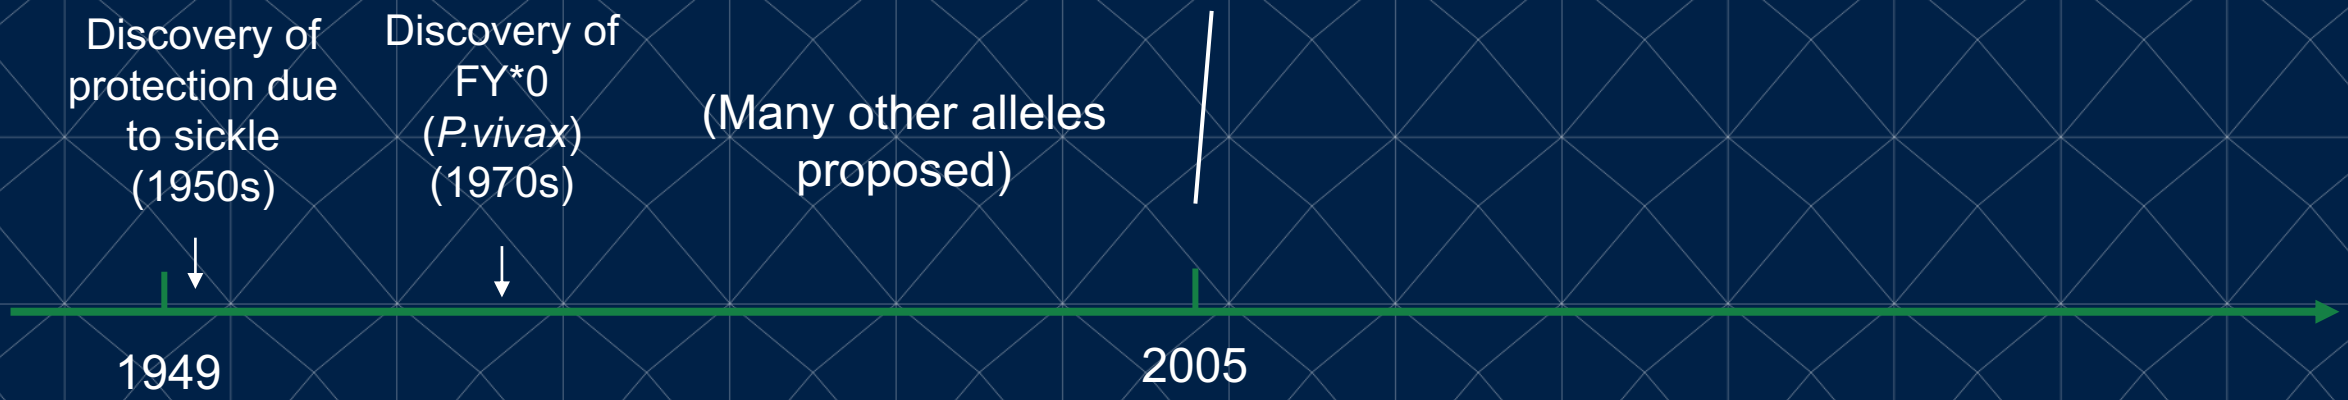
Cytoadhesion: *CD36*; *CR1*; *ICAM1*; *PECAM1*

Immunity: *FCGR2A*; *CD40* ligand Immune activation; HLA antigen presentation; Interferon receptor components; Interleukins

MBL2; *NOS2A*; Tumer Necrosis Factor; Interferon Gamma

"How Malaria Has Affected the Human Genome and What Human Genetics Can Teach Us about Malaria"
– Dominic Kwiatkowski Am J Hum Genet 2005

"When the same polymorphism has been tested in different geographical locations, the results have been variable - not simply failure to replicate but, in some cases, the association of the same polymorphism with susceptibility to severe malaria in one study and with resistance in another."



"How Malaria Has Affected the Human Genome and What Human Genetics Can Teach Us about Malaria"
– Dominic Kwiatkowski Am J Hum Genet 2005

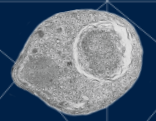
?



P.falciparum
23Mb genome
>5,000 genes
millions of variants

Have parasite populations adapted?

(And is this detectable in current populations?)

Human – *P.falciparum* genetic association study

"*Malaria protection due to sickle haemoglobin depends on parasite genotype*", 2021

https://doi.org/10.1038/s41586-021-04288-3

Plan of our analysis:

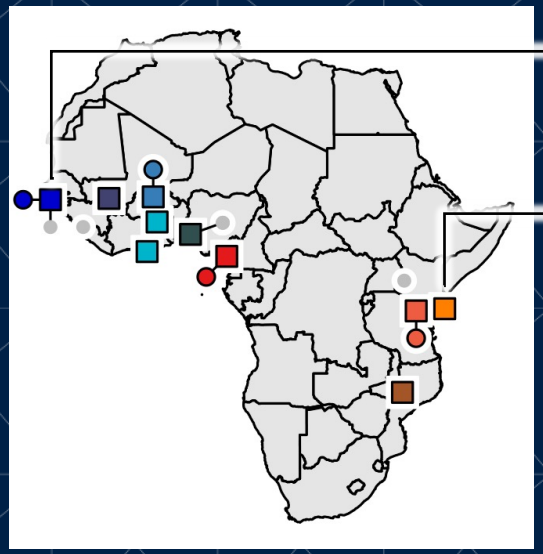
1. Sequence the *P.falciparum* genome in severe malaria cases
   selected from our previously published human GWAS*

2. Test for association between human and parasite genetic variants

*MalariaGEN human GWAS, Nature Communications 2019

Investigating human-parasite genetic interaction in severe malaria cases

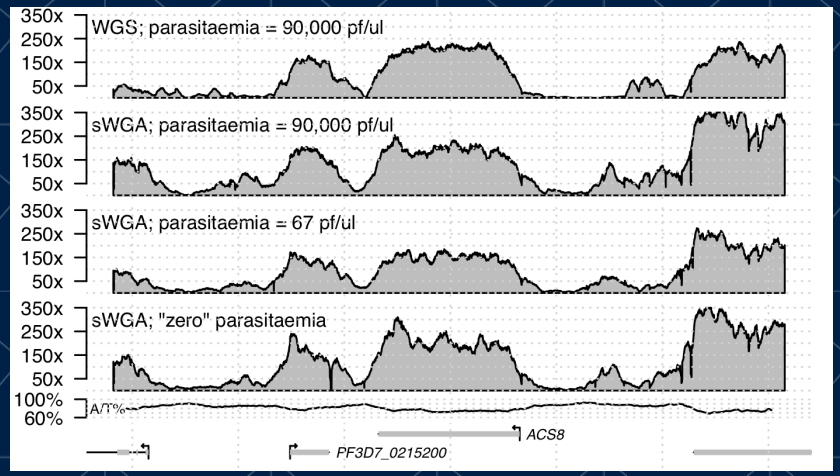
1. Sequence the *P.falciparum* genome in severe malaria cases from the published human GWAS



Banjul, The Gambia
N = 2,721

Kilifi, Kenya
N = 2,375

Collected in 1995-2009



Variant calling and quality control

Overlap with human data
N = 3,346 samples

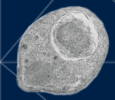
Previously generated human genome-wide genotypes and imputation

WELLCOME CENTRE *for* HUMAN GENETICS

2. Test for association pairwise between human and *Pf* variants using a simple logistic regression framework:

$$g_{Pf} \sim g_{\text{human}} + \text{country}$$

Software at: www.well.ox.ac.uk/~gav/hptest



Focus on candidates:

- Known protective mutations
- Further putative associations
- Blood group gene variants
- HLA alleles

Focus on 'easy' parts:

- Biallelic variants in core genome
- Seen in at least 25 infections across the sample.
- 51,552 variants in total

(...excludes multiallelics and complex regions)

?

”Reverse malaria hypothesis”

- *Pfsa*-carrying parasites are able to infect and cause disease in HbS-carrying individuals…

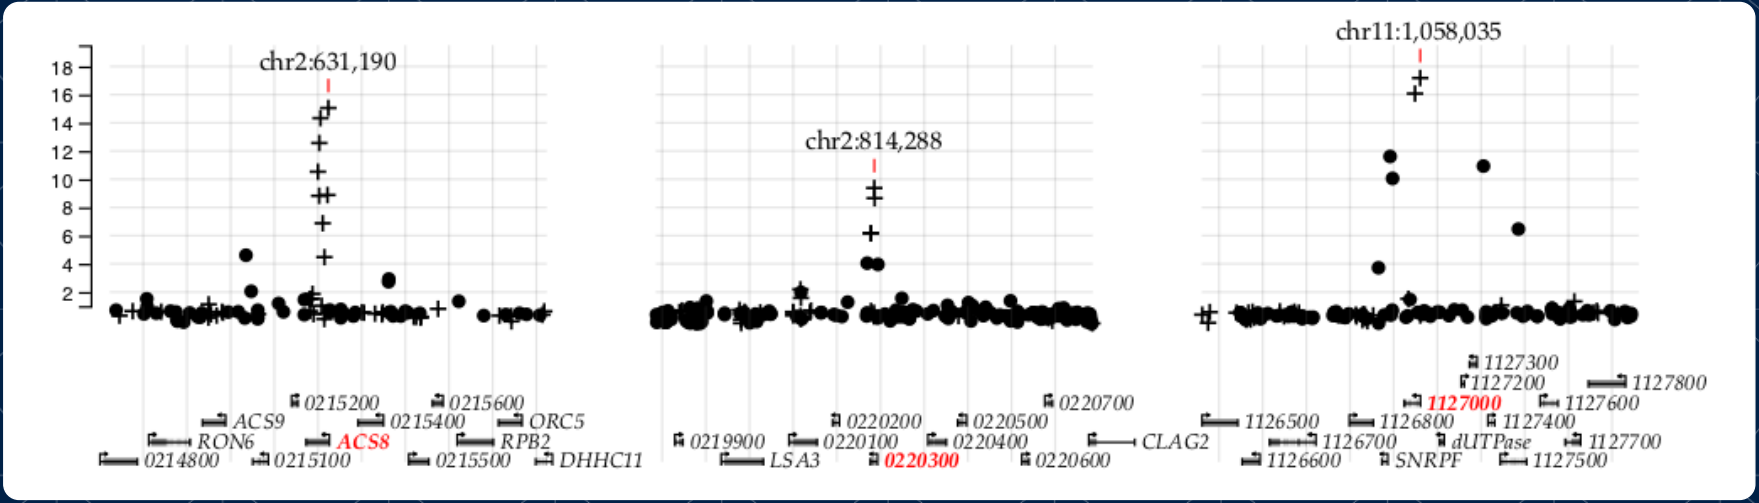
- …if so, they are presumably positively selected in individuals carrying HbS – a kind of reverse malaria hypothesis.

- This must be one of the selective forces generating the unusual population-genetic features - but any competing forces are currently unknown.

- Raises many questions…

Puzzles and questions

- What is the underlying biology?



The function of the *Pfsa* genes is not known

- How is the long-range LD maintained?
- What happens in other populations – or in milder cases?
- How does sickle provide protection anyway?
